Abstract: Recently, the disease by arteriosclerosis increases rapidly. Especially, the one that originates in hands and feet's peripheral arterial is called arteriosclerosis obliterans (ASO). The ASO is one of the typical diseases that cause a chronic ischemia of limbs and it leads to blood flow obstruction. In the diagnosis of ASO, lower contrast enhanced computed tomography (CT) is useful to observe artery. However it is huge task for radiologists to segment accurately only arteries, which they pay attention, from lower computed tomography angiography (CTA) by manual or semi-automatic with proprietary software. In this paper, we have developed a new technique for detection of the arteries from CTA images by use of a morphological operation. In this technique, the N-Quoit filter, that is a useful filter for detection lung nodules, is applied to identify the arteries in CTA images. Some experimental results were shown with a good performance of segmentation of arteries.

Keywords: contrast enhanced CT image, artery detection, segmentation, morphological filter

I. INTRODUCTION

Arteriosclerosis obliterans (ASO; it is also called PAD (peripheral arterial disease) or PVD (peripheral vascular disease) in USA) is one of the typical diseases that cause a chronic ischemia of limbs and it leads to blood flow obstruction. It is defined as an arteriosclerosis in which proliferation of the intima leads to occlusion of the lumen of the arteries. The ASO commonly shows its effects first in the legs and feet. The narrowing of the arteries may progress to total closure of the vessel. This disease is caused by diabetes, hyperlipemia, hypertension and smoking. Intermittent claudicating is the most symptoms of ASO [1] and large experiment in the USA showed that the incidence of male and female with the age of 50 to 70 is 5 to 8 per 1,000 populations for the year.

In the diagnosis of ASO, it is useful for detection of arteries by use of computed tomography angiography (CTA) and magnetic resonance angiography (MRA). In Addition, fresh blood imaging (FBI) is a very useful imaging diagnosis method which is obtained by magnetic resonance (MR) imaging without using contrast media. It is also can be analyzed arteries on the anatomical structure in which are enhanced on the images [2]. Especially, three dimensional (3-D) images reconstructed by using some rendering methods from two dimensional (2-D) medical images are needed for observation and intervention of the arteries. On the other hand, detection and/or segmentation of the arteries from CTA, MRA and MR image from FBI are important task for these scenes. It is, however, there is a considerable issue that radiologists require much time for reconstruction as a 3D image or display it. Hence, it burdens to segment the arteries from medical images manually or semi-automatically using some proprietary software.

To overcome this problem, many researchers have studied about automatic detection/segmentation techniques of blood vessels from medical images and some result showed relatively good performance [3]. However the studies about

detection of arteries in lower CTA images have almost not reported. In this paper, we have developed a new technique for detection of the arteries from contrast-enhanced lower CT images by use of a morphological operation. In this technique, N-Quoit filter, which is widely introduced as a useful filter for detection lung nodules [4], is applied to identify the arteries in CT images. In this paper, the technique has been evaluated by applying for actual two CTA image sets. Some experimental results were shown with a good performance of detection of arteries. As we mentioned above, this technique provided as one of the powerful CAD system in medical field. One of the benefits of using this technique is that analyzing of arteries on the anatomical structure can be simplified. Also we believe the technique make it possible to improve the detectability of arteries in order to diagnosis of ASO.

II. MATERIALS AND METHODS

Figure 1 shows the CTA images which is employed in this study. In Fig.1, some artery areas are indicated with arrows. The aim in this study is to detect the region of arteries such as anterior tibial artery, posterior tibial artery, and fibular artery in CTA images automatically. The computerized scheme of this study is shown in Fig. 2. At first, preprocessing is performed to segment the bone regions. In the next step, we identify initial point as a location of the artery on the top of image sets by using mouse point manually for tracing/detecting the artery areas in the next slices, automatically. The trace of arteries are performed by search of maximum output value of the N-Quoit filter. This trace is continued from the second number of slice to the end of slice. Finally the detected arteries areas are displayed as a 2-D or 3-D image.

1. N-Quoit filter

N-Quoit filter have been proposed as a filter which enhances lung nodules in multi-detector row CT [4]. The filter, that is a kind of morphological filters, is sensitive for the distribution of pixels like a circle in the 2-D image. Figure 3 shows the basic concept of the N-Quoit filter. With shown in Fig.3, the N-Quoit filter consists of two kinds of filter, a point filter and a disk filter. If these filters overlay an object like a circle, then only the ring filter falls and vertical interval has large value. On the other hand, in the case of some objects not like a circle, the ring filter does not fall as well the point filter and vertical interval has small value. The output value of the N-Quoit filter is subtracted value of dilation operation with these filters. Following expressions show the output of the N-Quoit filter.

$$\begin{aligned} q(x, y) &= f(x, y) \oplus P(x_1, y_1) - f(x, y) \oplus R(x_1, y_1) \\ &= f(x, y) - f(x, y) \oplus R(x_1, y_1) \end{aligned} \quad (1)$$

$$f(x, y) \oplus R(x_1, y_1) = \max_{(x_1, y_1) \in K_r} \{f(x - x_1, y - y_1) + R(x_1, y_1)\} \quad (2)$$

Where $q(x,y)$ and $f(x,y)$ show an output and input image, respectively. $P(x_1,y_1)$ and $R(x_1,y_1)$ show a point and ring filter function, respectively. Furthermore K_r shows the domain of these filters. “ \oplus ” shows dilation operation in morphology.

Ring filter function $R(x_1,y_1)$ is expressed as following.

$$R(x_1, y_1) = \begin{cases} 0 & \text{if } r_1^2 < x_1^2 + y_1^2 \leq r_2^2 \\ -\infty & \text{otherwise} \end{cases} \quad (3)$$

Where, r_1 and r_2 show the internal and external diameter of the ring filter. In the CTA images, artery areas are appeared in the form of a circle. Applying the N-Quoit filter for CTA images, the location of the arteries should have higher value of the output image (See in Fig.4 with the arrow).

2. Detection of arteries employing N-Quoit filter

It is possible to identify arteries by search of the maximum value of output of the N-Quoit filter. In this paper, some arteries are detected from CTA images by following computerized scheme; first, initial location of an artery is identified on the top of image sets, manually. In the next step, a search region is located on the selected location. In the search region, a location having the maximum output value of the N-Quoit filter is identified as center of the artery. The identified location is determined as the center of search region in the next slice. These processes are continued to the end of slices or the subtracted value of output over the successive slices is less than threshold. However, it might be difficult to identify a location as an artery adjacent to bone. It is because that there are no differences of voxel value between the edge of bone and arteries. To overcome this problem, in this paper, bone regions are segmented from the CTA images based on following steps previously to avoid mis-detection of the arteries.

3. Segmentation of bone region from CTA image

For segmentation of the bone region, threshold method and distance transformations are applied to CTA image. Our segmentation method consists of two steps; rough segmentation of bone region based on threshold and fine segmentation of bone region based on distance map. In the rough segmentation, at first, binarization is applied on original CTA image (Fig.5(a)) with threshold which is determined empirically (Fig.5(b)). At this point, the threshold is relatively higher value for segmentation of internal bone region from CTA images. In the next step, an inner region of the binarized region is also segmented as bone region by using dilation processing (Fig.5(c)). To determine more suitable boundary of bone region, we analyze voxel average on a distance map. Distance map is obtained from the dilated image (Fig.5(c)) by using a distance transformation. At this point, voxel value on the border of bone region

should have almost same value for identical structures/object on the image. Moreover, at the border, the average of voxel value would be decreased broadly (Fig.6). So, we can obtain thresholds of TH1 and TH2 for average value and distance value, respectively. Finally, we can obtain bone mask $M(x,y)$ from distance map $D(x,y)$ from

$$M(x,y) = \begin{cases} 1 & \text{if } D(x,y) < TH2 \\ 0 & \text{otherwise} \end{cases} \quad (4)$$

III. EXPERIMENT

In this paper, the technique has been evaluated by applying for two CTA image sets. Image size is 512 x 512[pixels] and the image sets consist of 181 and 156 slices images, respectively. The slice thickness is 2.0[mm] and pixel spacing is 0.528 x 0.528[mm]. The mask size is 11 x 11[pixel] and the size of r_1 and r_2 in equation 3 are 3 and 4, respectively. Threshold for binarization is 1000 [H.U.]. Threshold of termination condition for trace of arteries is determined -300 empirically.

Figure 7 shows experimental results of detection of arteries. In Fig. 7, each rectangle regions on the image are shown the selected locations by manually and automatically. In Fig.7, it is apparent that some arteries adjusted by bone regions accurately. Figure 8 shows the 3-D image of detected arteries enhanced by red color. In Fig.8, some arteries are displayed accurately apart from other structures. Figure 9 shows the distribution of output of N-Quoit filter in the case of segmentation or non-segmentation of bone region. As shown Fig.9, the output of N-Quoit filter dropped broadly in the case of non-segmentation of bone region, because the bone regions were segmented accidentally. On the other hand, in the case of segmentation of bone region, we could avoid mis-segmentation for bone region, shown Fig.9. For evaluation of detection of arteries, we calculate the accuracy of arteries by using following expression.

$$Accuracy = \frac{Detected\ arteries \cap Gold\ standard}{Gold\ standard} \times 100 \quad (5)$$

The accuracy of extracted arteries is shown in Table 1. The accuracy shows that artery in the 2-D image is exactly identified. As shown in Table1, we achieved good results of segmentation of bone region. The average of the accuracy was 91.5[%] and computational times was 30[sec/case]. However, in Table1, the accuracy is degraded in identification of right artery fibular and right posterior artery. This false identification can be caused by mis-segmentation of bone and for branch of arteries.

IV. CONCLUSION

In this paper, we have developed a new technique for detection of the arteries from contrast enhanced lower CT image by use of morphological operation. Some experimental results were shown with a good performance of segmentation of arteries. However, some cases include mis-detections of the arteries from CTA images. In general, there is no difference of voxel value between the border of bones and arteries, and, therefore, we need to some models of bones or artery to segment accurately from CTA. It still remains as one of future works.

In this paper, a morphological filter is applied to detect arteries on consideration for shape of arteries like as a circle. It will be possible to apply for other parts of body, however, more accurate for detection algorithms are needed for the branch of arteries. Solving some technical issues for detection arteries, it will be possible to reduce of burden of radiologist and to develop a system for detection of constriction of arteries.
